CLINICALLY RELEVANT RESULTS

Tier I - Strong Clinical Significance

VARIANT

INTERPRETATION

NCOA4-RET fusion

RET encodes a receptor tyrosine kinase involved in cell growth and differentiation which is known to undergo oncogenic activation in vivo and in vitro by cytogenetic rearrangement (provided by RefSeq, Jul 2008). NCOA4 encodes an androgen receptor coactivator which interacts with the androgen receptor in a ligand-dependent manner to enhance its transcriptional activity. Chromosomal translocations between NCOA4 and RET, both located on chromosome 10, have been associated with papillary thyroid carcinoma (provided by RefSeq, Feb 2009).

RET rearrangements resulting in fusion with partner genes including KIF5B, CCDC6 and NCOA4 have been reported in non-small cell lung cancer (NSCLC) patients(PMID- 29128428). A NCOA4-RET fusion is identified in this case. The N terminus of the NCOA4 gene fuses with the C terminus of the RET gene in this fusion (PMID- 28011461). In PCCL3 cells, expression of NCOA4-RET fusion was reported to simultaneously activate DNA synthesis and apoptosis apart from interfering with thyroid differentiation at steps distal to the TSH-R (PMID- 12690093, 2003). The NCOA4-RET fusion has been reported in patients with NSCLC specifically in lung adenocarcinoma patients (COSMIC, February 2019, PMID- 23150706). RET rearrangements are one of the emerging biomarkers to identify novel therapies for patients with metastatic NSCLC (NCCN, NSCLC v.3.2019). NCCN recommends cabozantinib and vandatinib (category 2A) as targeted agents for NSCLC patients harbouring RET rearrangements (NCCN, NSCLC v.3.2019).

p.G12D c.35G>A

NM_004985.3 VAF % 10.0 DEPTH 5663 The KRAS protein has intrinsic GTPase activity and is an important mediator of growth factor receptor signaling resulting in the activation of several downstream pathways such as PI3K-mTOR and RAS-RAF-MEK pathway (RefSeq, Jul 2008).

A missense alteration in KRAS, G12D, is identified in this case. Codon 12 lies within a GTP binding region of the KRAS protein (UniProt.org). Mutations in KRAS at codon 12 (within the GTP binding region), including KRAS G12D, result in reduced GTPase activity, which in turn leads to constitutive activation of KRAS and its downstream PI3K-AKT and MAPK signaling pathways (PMID- 26902995; 25705018).

In ClinVar, KRAS G12D has been classified as 'Pathogenic' in several malignancies ('Pathogenic' for somatic in malignancies including non-small cell lung cancer) (Variation ID: 12582). KRAS G12D is reported in malignancies including non-small cell lung cancer (COSMIC, February 2019). Approximately 25% of patients with lung adenocarcinomas in a North American population have KRAS mutations (NCCN, NSCLC v3.2019). KRAS mutation prevalence has been associated with cigarette smoking (NCCN, NSCLC v3.2019).

In NSCLC, the presence of a KRAS mutation is prognostic of poor survival when compared to patients with tumors without KRAS mutation, independent of therapy (NCCN, NSCLC v3.2019). KRAS mutations have a predictive role in brain metastases incidence, recurrence and outcome in Caucasian NSCLC patients (PMID- 27999344; 26616848). Mutations in KRAS have been associated with reduced responsiveness to EGFR TKI therapy and do not appear to affect chemotherapeutic efficacy (NCCN, NSCLC v3.2019). Targeted therapy is currently not available for patients with KRAS mutations, although immune checkpoint inhibitors appear to be effective; MEK inhibitors are in clinical trials (NCCN, NSCLC v3.2019).

Tier II - Potential Clinical Significance

VARIANT

INTERPRETATION

p.D842V c2525A>T

NM_006206.4 VAF % 15.0 DEPTH 7986 PDGFR-alpha (PDGFRA) is a receptor protein kinase that activates the PI3K/AKT/mTOR and MAPK/ERK pathways and promotes activation of STAT family members STAT1, STAT3 and STAT5A and/or STAT5B (UniProt.org).

A missense alteration in PDGFRA, D842V, is identified in this case. Codon 842 lies in exon 18, within the protein kinase domain of PDGFRA (UniProt.org). PDGFRA D842V is reported to be an activating, in vitro (PMID- 27349873; 12949711, 2003). In ClinVar, somatic PDGFRA D842V is reported as 'Pathogenic' in gastrointestinal stromal tumor (GIST) (Variation ID: 13543).

PDGFRA D842V has been reported in Non-small cell lung cancer (COSMIC, February 2019). About 5% to 10% of GISTs have a mutation in the gene encoding PDGFRA receptor tyrosine kinase and PDGFRA exon 18 mutations are common in gastric GISTs (NCCN, Soft Tissue Sarcoma, v1.2019). Identification of activating kinase mutations in PDGFRA is an ancillary technique useful in the diagnosis of sporadic and familial GIST (NCCN, Soft Tissue Sarcoma, v1.2019).

PDGFRA exon 18 mutations (including D842V) are associated with a better prognosis in GIST patients (NCCN, Soft Tissue Sarcoma, v1.2019). Primary imatinib resistance is commonly seen in GIST patients with mutations including PDGFRA D842V (NCCN, Soft Tissue Sarcoma,v1.2019; PMID- 30506540). A small number of GIST patients with a primary or secondary D842V mutation did not respond to sunitinib treatment (NCCN Soft Tissue Sarcoma v1.2019; PMID- 30224936). Dasatinib has demonstrated activity against PDGFRA D842V mutation, and it could be an effective treatment option for imatinib-resistant GIST patients (NCCN, Soft Tissue Sarcoma v1.2019).

Other Biomarkers

TMB
Tumor mutational burden is an emerging quantitative genomic biomarker used to predict sensitivity to checkpoint inhibitors. NCCN recommends nivolumab with or without ipilimumab for patients with high TMB based on a recent study and the results of a Phase III clinical trial, NCT02477826 (NSCLC v3.2019, PMID: 29658845, 28636851)

IVISI

Stable

5%

Unstable Sites

Microsatellite Instability is caused by a failure of the DNA mismatch repair system (MMR) and a predictor of favorable response to immunotherapies (PMID: 26028255). This patient does not exhibit evidence of High Microsatellite Instability (MSI).

CLASSIFICATION AND LEVELS OF EVIDENCE

The variant classification system used in this report is based on joint consensus recommendations of the Association for Molecular Pathology, American Society of Clinical Oncology, and the College of American Pathologists (J Mol Diagn 2017, 19:4-23). Tiers IA, IB, IIC, IID, III and IV describe variant categories of descending clinical significance in the patient. Variants in Tier IV are not reported in accordance with the consensus recommendations.

IA

Variant of strong clinical significance, Level A evidence (FDA approved therapy or practice guideline in patient's tumor type)

ΙB

Variant of strong clinical significance, Level B Evidence (consensus in the field based on well-powered studies in patient's tumor type)

IIC

Variant of potential clinical significance, Level C evidence (FDA approved therapy or practice guideline in other tumor type(s), evidence from multiple small published studies, or based on availability of investigational therapies)

IID

Variant of potential clinical significance, Level D evidence (case reports or preclinical studies)

Ш

Variant of unknown clinical significance

Benign or likely benign variant

METHODOLOGY

Experimental Methodology: This test uses targeted next-generation sequencing to analyze coding regions of the most inclusive annotated RefSeq transcript for each of the targeted genes. Target enrichment was performed using TruSight Oncology 500 workflow (Illumina). Sequencing of enriched libraries was performed in multiplex on the Illumina NextSeq using the paired-end, 150 base-pair configuration.

Informatics Methodology: Secondary analysis was performed using Illumina's TruSight Oncology 500 Local App version 1.3.1.

DISCLAIMER

This Report was generated using the materials and methods described below, which required the use of various reagents, protocols, instruments, software, databases, and other items, some of which were provided or made accessible by third parties. A defect or malfunction in any such reagents, protocols, instruments, software, databases, and/or other items may compromise the quality or accuracy of the Report.
